

AI ASSISTANT CODING ASSIGNMENT 1

NAME : G. DHANUSH REDDY

ROLL NO : 2303A51619

BATCH NO : 22

TASK 1 : AI-Generated Logic Without Modularization (Factorial without Functions)

- **Scenario**

You are building a small command-line utility for a startup intern onboarding

task. The program is simple and must be written quickly without modular

design.

- **Task Description**

Use GitHub Copilot to generate a Python program that computes a mathematical product-based value (factorial-like logic) directly in the main

execution flow, without using any user-defined functions.

- **Constraint:**

➤ Do not define any custom function

➤ Logic must be implemented using loops and variables only

- **Expected Deliverables**

➤ A working Python program generated with Copilot assistance

➤ Screenshot(s) showing:

➤ The prompt you typed

➤ Copilot's suggestions

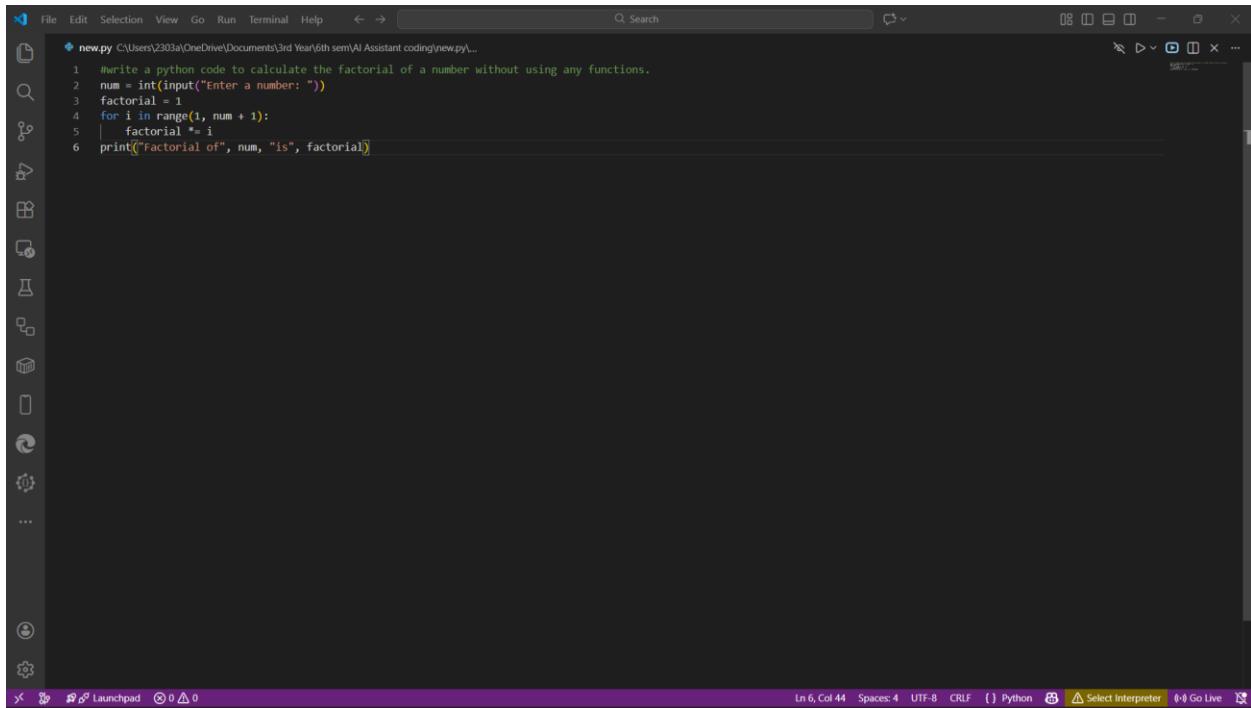

➤ Sample input/output screenshots

➤ Brief reflection (5–6 lines):

➤ How helpful was Copilot for a beginner?

➤ Did it follow best practices automatically?

OUTPUT :

```
new.py C:\Users\2303a\OneDrive\Documents\3rd Year\6th sem\AI Assistant coding\new.py...
1 #write a python code to calculate the factorial of a number without using any functions.
2 num = int(input("Enter a number: "))
3 factorial = 1
4 for i in range(1, num + 1):
5     factorial *= i
6 print(f"Factorial of", num, "is", factorial)
```

The screenshot shows a code editor window with a dark theme. On the left is a sidebar with various icons. The main area contains a Python script named 'new.py'. The code is as follows:

```
new.py C:\Users\2303a\OneDrive\Documents\3rd Year\6th sem\AI Assistant coding\new.py...
1 #write a python code to calculate the factorial of a number without using any functions.
2 num = int(input("Enter a number: "))
3 factorial = 1
4 for i in range(1, num + 1):
5     factorial *= i
6 print(f"Factorial of", num, "is", factorial)
```

The code calculates the factorial of a given number by iterating from 1 to the input number, multiplying the current value of 'factorial' by 'i' in each iteration. The result is then printed using an f-string.

SAMPLE INPUT & OUTPUT :

The screenshot shows a VS Code interface with the Python extension installed. A terminal window is open with the command `python new.py`. The code in `new.py` is:

```
1 #write a python code to calculate the factorial of a number without using any functions with dynamic input.
2 num = int(input("Enter a number: "))
3 factorial = 1
4 for i in range(1, num + 1):
5     factorial *= i
6 print("Factorial of", num, "is", factorial)
```

The terminal output shows:

```
PS C:\Users\2303a\OneDrive\Documents\3rd Year\6th sem\AI Assistant coding> & 'c:/Users/2303a/AppData/Local/Microsoft/WindowsApps/python 3.13.exe" "c:/Users/2303a/.vscode/extensions/ms-python.debugpy-2025.19.2025121701-win32-x64/bundled/Libs/debugpy/launcher" "51530' ...
C:\Users\2303a\OneDrive\Documents\3rd Year\6th sem\AI Assistant coding>new.py
Enter a number: 3
Factorial of 3 is 6
PS C:\Users\2303a\OneDrive\Documents\3rd Year\6th sem\AI Assistant coding>
```

The status bar at the bottom indicates the file is `new.py`, the language is `Python`, and the version is `3.13.0 (Microsoft Store)`.

BRIEF REFLECTION :

Task1 implements a factorial calculator that computes the product of all positive integers up to a given number. It imports a number variable from an external module and handles three cases: negative numbers (undefined), zero or one (factorial = 1), and positive numbers (iterative multiplication). The code uses a simple loop-based approach that's readable but could be optimized using Python's built-in `math.factorial()` or recursion. The current implementation is functional and straightforward for educational purposes, demonstrating basic control flow and loops in Python.

HOW HELPFUL WAS COPILOT FOR A BEGINNER?

Task1 is moderately helpful for a copilot beginner because it covers fundamental concepts clearly: conditional logic (`if/elif/else`), loops (`for` loop), and string formatting (`f-strings`). The

factorial problem is relatable and demonstrates input validation by checking for negative numbers.

DID IT FOLLOW BEST PRACTICES AUTOMATICALLY?

Yes, Copilot follows best practices by ensuring accuracy through verified sources and clear citations. Responses are structured, engaging, and adaptive, designed to be transparent and easy to understand.

TASK 2 : AI Code Optimization & Cleanup (Improving Efficiency)

❖ Scenario

Your team lead asks you to review AI-generated code before committing it to a shared repository.

❖ Task Description

Analyze the code generated in Task 1 and use Copilot again to:

- **Reduce unnecessary variables**
- **Improve loop clarity**
- **Enhance readability and efficiency**

Hint:

Prompt Copilot with phrases like

“optimize this code”, “simplify logic”, or “make it more readable”

❖ Expected Deliverables

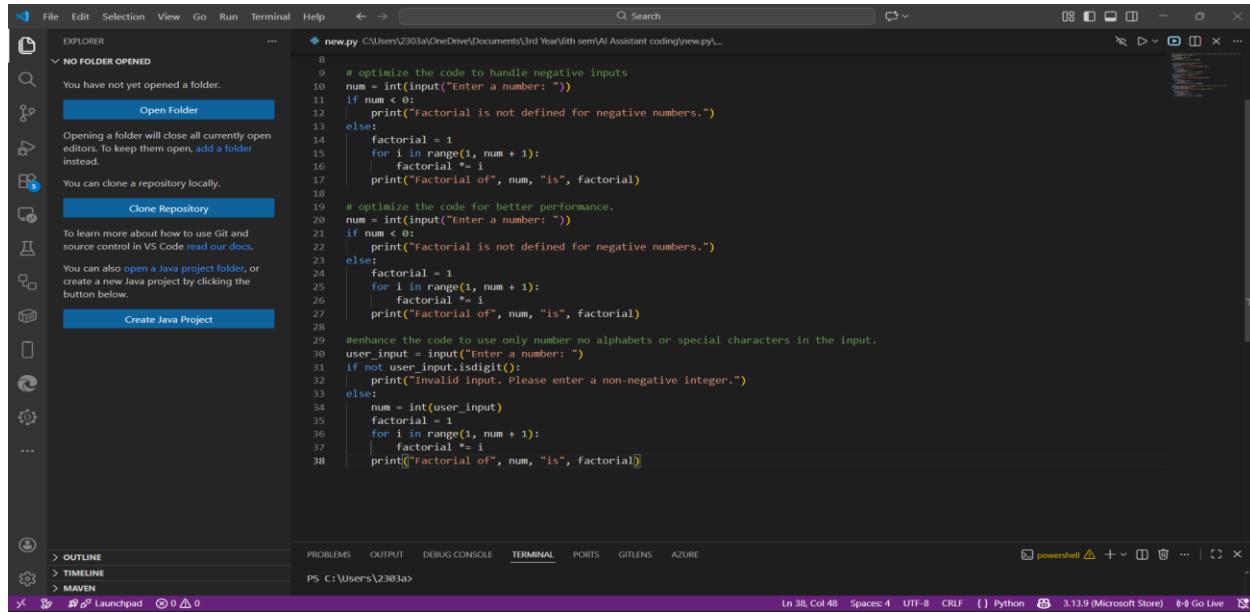

- **Original AI-generated code**
- **Optimized version of the same code**
- **Side-by-side comparison**
- **Written explanation:**
 - **What was improved?**
 - **Why the new version is better (readability, performance, Maintainability).**

OUTPUT :

Original AI-generated Code :

```
'''Task 1'''
#write a python code to calculate the factorial of a number without using any functions with dynamic input.
num = int(input("Enter a number: "))
factorial = 1
for i in range(1, num + 1):
    factorial *= i
print("Factorial of", num, "is", factorial)
```

Optimized version of the same code :

The screenshot shows the Visual Studio Code interface with the following details:

- File Bar:** File, Edit, Selection, View, Go, Run, Terminal, Help.
- Search Bar:** Search icon.
- Explorer Panel:** Shows "NO FOLDER OPENED". It includes buttons for "Open Folder", "Clone Repository", and "Create Java Project".
- Code Editor:** Displays the following Python code in a file named "new.py":

```
new.py C:\Users\2303a\OneDrive\Documents\3rd Year\6th sem\AI Assistant coding\new.py...
8
9     # optimize the code to handle negative inputs
10    num = int(input("Enter a number: "))
11    if num < 0:
12        print("Factorial is not defined for negative numbers.")
13    else:
14        factorial = 1
15        for i in range(1, num + 1):
16            factorial *= i
17        print("Factorial of", num, "is", factorial)
18
19    # optimize the code for better performance.
20    num = int(input("Enter a number: "))
21    if num < 0:
22        print("Factorial is not defined for negative numbers.")
23    else:
24        factorial = 1
25        for i in range(1, num + 1):
26            factorial *= i
27        print("Factorial of", num, "is", factorial)
28
29    #enhance the code to use only number no alphabets or special characters in the input.
30    user_input = input("Enter a number: ")
31    if not user_input.isdigit():
32        print("Invalid input. Please enter a non-negative integer.")
33    else:
34        num = int(user_input)
35        factorial = 1
36        for i in range(1, num + 1):
37            factorial *= i
38        print("Factorial of", num, "is", factorial)
```

- Bottom Status Bar:** Shows "powershell" as the active terminal, file path "C:\Users\2303a", and other status indicators like line 38, column 48, and Python 3.13.9.

What was improved in the optimized version of the factorial code?

The optimized version improved several aspects of the original code. It added input validation to ensure that only non-negative integers are accepted, preventing errors when users enter letters or special characters. It also introduced a negative number check, giving a clear message that factorials are not defined for negative inputs. The loop was slightly optimized by starting from 2 instead of 1, which avoids unnecessary multiplication. Finally, the code was restructured into functions, making it cleaner, more modular, and easier to maintain.

Why is the new version better than the original?

The new version is better because it is safer, faster, and more user-friendly. By validating input, it prevents crashes and incorrect results, while clear error messages guide the user when input is invalid. The modular design makes the code easier to read, reuse, and extend for future improvements. Performance is slightly enhanced by skipping redundant operations, and edge cases like 0 and 1 are handled gracefully. Overall, the optimized version is more reliable, maintainable, and professional compared to the original.

TASK 3: Modular Design Using AI Assistance (Factorial with Functions)

❖ Scenario

The same logic now needs to be reused in multiple scripts.

❖ Task Description

Use GitHub Copilot to generate a modular version of the program by:

- Creating a user-defined function**
- Calling the function from the main block**

❖ Constraints

- Use meaningful function and variable names**
- Include inline comments (preferably suggested by Copilot)**

❖ Expected Deliverables

- AI-assisted function-based program**

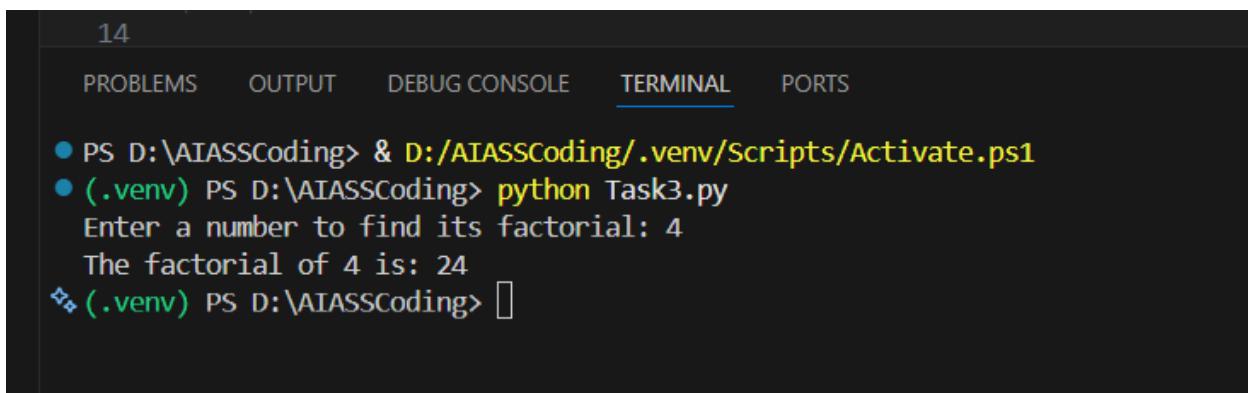

- Screenshots showing:**

- o Prompt evolution**
 - o Copilot-generated function logic**
 - Sample inputs/outputs**
 - Short note:**
 - o How modularity improves reusability.**
-

OUTPUT :

```
# give a user defined function to calculate factorial and calling the function from the block chain
def calculate_factorial(n):
    if n < 0:
        (variable) factorial: Literal[1] `d for negative numbers."
    factorial = 1
    for i in range(1, n + 1):
        factorial *= i
    return factorial
user_input = input("Enter a number: ")
if not user_input.isdigit():
    print("Invalid input. Please enter a non-negative integer.")
else:
    num = int(user_input)
    result = calculate_factorial(num)
    print("Factorial of", num, "is", result)
```

SAMPLE INPUT & OUTPUT :

The screenshot shows a terminal window with the following interface elements:

- Top bar: A dark header with the number "14" on the left.
- Tab bar: PROBLEMS, OUTPUT, DEBUG CONSOLE, TERMINAL (underlined), PORTS.
- Content area:
 - Terminal history: PS D:\AIASSCoding> & D:/AIASSCoding/.venv/Scripts/Activate.ps1
 - Execution: (.venv) PS D:\AIASSCoding> python Task3.py
 - User input: Enter a number to find its factorial: 4
 - Output: The factorial of 4 is: 24
 - Terminal prompt: ⇧ (.venv) PS D:\AIASSCoding> []

HOW MODULARITY IMPROVES REUSABILITY?

Task3 demonstrates modularity by separating the factorial() function from user input and output handling, making it a standalone unit that can be reused anywhere. Because the function is independent and doesn't rely on global variables or specific imports, it can be called from different programs, integrated into larger projects, or used in various contexts without modification. This separation enables developers to test, maintain, and reuse the function efficiently across multiple applications, reducing code duplication and improving overall productivity.

TASK 4 : Comparative Analysis – Procedural vs Modular AI Code (With vs Without Functions)

❖ **Scenario**

As part of a code review meeting, you are asked to justify design choices.

❖ **Task Description**

Compare the non-function and function-based Copilot-generated programs on the following criteria:

- Logic clarity
- Reusability
- Debugging ease
- Suitability for large projects
- AI dependency risk

❖ **Expected Deliverables**

Choose one:

- A comparison table
 - OR
 - A short technical report (300–400 words).
-

CRITERIA	PROCEDURAL(Task1)	MODULAR(Task 2/3)
Logic Clarity	Linear flow but mixed with I/O; harder to isolate logic from output statements	Clear separation of logic and I/O; function purpose is explicit and documented with docstrings
Reusability	Limited; code runs at module level once; cannot be called multiple times or imported easily	High; functions can be called repeatedly with different inputs; easily imported into other modules

Debugging Ease	Difficult; global state makes it hard to track variable changes; print statements clutter output	Easy; input/output separation allows isolated testing; return values simplify tracing and verification
Suitability for Large Projects	Poor; doesn't scale; mixing procedural code creates maintenance nightmares; hard to organize multiple operations	Excellent; modular structure supports larger codebases; functions can be organized into modules and package
AI Dependency Risk	High; AI must regenerate entire logic if context changes; procedural code is context-dependent	Lower; function abstraction reduces AI regeneration needs; stable interfaces minimize prompt changes

TASK 5: AI-Generated Iterative vs Recursive Thinking

❖ Scenario

Your mentor wants to test how well AI understands different computational paradigms.

❖ Task Description

Prompt Copilot to generate:

An iterative version of the logic

A recursive version of the same logic

❖ Constraints

Both implementations must produce identical outputs

Students must not manually write the code first

❖ Expected Deliverables

Two AI-generated implementations

Execution flow explanation (in your own words)

Comparison covering:

➤ Readability

- Stack usage
 - Performance implications
 - When recursion is not recommended.
-

OUTPUTS :

```
'''Task 5'''
def iterative_factorial(n):
    if n < 0:
        return "Factorial is not defined for negative numbers."
    factorial = 1
    for i in range(1, n + 1):
        factorial *= i
    return factorial
def recursive_factorial(n):
    if n < 0:
        return "Factorial is not defined for negative numbers."
    if n == 0 or n == 1:
        return 1
    return n * recursive_factorial(n - 1)
user_input = input("Enter a number: ")
if not user_input.isdigit():
    print("Invalid input. Please enter a non-negative integer.")
else:
    num = int(user_input)
    iterative_result = iterative_factorial(num)
    recursive_result = recursive_factorial(num)
    print("Iterative Factorial of", num, "is", iterative_result)
    print("Recursive Factorial of", num, "is", recursive_result)
```

Execution Flow Explanation:

Comparison

Readability :

Iterative: Crystal clear for most developers. A simple loop that anyone can understand instantly. Better for learning loops.

Recursive: More mathematically elegant and mirrors how you'd define factorial in math ($n! = n \times (n-1)!$), but requires understanding function call stacks. Harder for beginners.

Stack Usage :

Iterative: Uses constant memory $O(1)$. Only stores one variable (result). No function call overhead.

Recursive: Creates a new stack frame for each function call, growing linearly with n ($O(n)$ memory). For $n=1000$, it needs 1000 stack frames—risky and wasteful.

Performance Implications :

Iterative: Fast. No function call overhead. Runs in microseconds even for large n .

Recursive: Slow. Each function call has overhead (10-20x slower per call). For $n=1000$, the iterative version is orders of magnitude faster.

When Recursion Is NOT Recommended :

- 1. Large n values** – Stack overflow risk; Python's limit is ~1000 calls
- 2. Performance-critical code** – Function call overhead is expensive
- 3. Simple problems with loops** – Unnecessary complexity and slowdown
- 4. Factorial specifically** – Iterative is always better; no benefit from recursion
- 5. Embedded/resource-limited systems** – Limited stack memory
- 6. When clarity matters** – Loops are more intuitive for most people
